

Project 1:

Truncated Icosahedron

Volume Challenge:
Find the optimal shape
to maximize the ratio

Sketching & Prototyping

Initial Sketches

Between ease of manufacturing vs. SA-V, I prioritized SA-V. With the most optimal SA-V ratio being a **sphere**, I started by thinking of what were **sphere-adjacent shapes**.

Geodesic dome with a hexagonal base:
Cool, but difficult to design and assemble, good SA-V ratio.

Hexagonal Prism: Easy to design and assemble, bad SA-V ratio, standard design

In order to maximize SA-V ratio, had to sacrifice ease in building.

Truncated Icosahedron:

- Maximized SA-V ratio
- Easy to design (2 shapes & symmetric)
- Possible difficult assembly

Joints

a) **Single Dovetail** – Very secured when interlocked, difficult to do with shape's angle.

b) **Single Friction Fit** – Small surface area, so lower friction, which increases the chances of the object falling apart

c) **Double Friction Fit** – Doubled the surface area, so doubled the friction; ensures interlocking between shapes → more security.

Prototyping

Used the prototype to experiment with joints & found that dovetails work perfectly for 90°, but nothing else. Whereas, friction works for all sorts of angles, if done right.

Final Design

Truncated icosahedron:

- 20 hexagonal pieces
- 12 pentagonal pieces
 - 5 with outer, 7 with only inner
- Double friction fit
- ~ 5.5 inches tall, so 1 inch edges

Building & Calculations

SA-V Ratio

Surface Area:

5 in 0 out x 7

3 in 2 out x 5

2 in 4 out x 20

side-length = 1"

single in-tab 0.14"

single out-tab 0.14"

0.216"

Pent: $\frac{1}{4} \sqrt{5(5+2\sqrt{5})} a^2$

Hex: $\frac{3\sqrt{3}}{2} a^2$

Volume:

$V = \frac{1}{4} (125 + 43\sqrt{5})$

Equation from Wolfram Alpha Website

* Assume perfect truncated icosahedron for calculations

$V = 55.29 \text{ in}^3$

in-pent: $\frac{1}{4} \sqrt{5(5+2\sqrt{5})} (1")^2$

out-pent: $\frac{1}{4} \sqrt{5(5+2\sqrt{5})} (1")^2$

$\approx 1.72 \text{ in. sq.}$

$\approx 1.72 \text{ in. sq.}$

$\approx 1.72 - 6(0.14 \cdot 0.2)$

$+ 4(0.14 \cdot 0.216)$

$\approx 1.72 - 0.84 + 0.121$

$\approx 1.001 \text{ in}^2$

Hex: $\frac{3\sqrt{3}}{2} a^2 \approx 2.6 \text{ in. sq.}$

$\approx 2.6 - 4(0.14 \cdot 0.2) + 8(0.14 \cdot 0.216)$

$\approx 2.6 - 1.12 + 2.42$

$\approx 3.9 \text{ in}^2$

Total area:

$10.08 \text{ in}^2 + 8.36 \text{ in}^2 + 54.60 \text{ in}^2$

$= 73.04 \text{ in}^2$

SA-V ratio:

$73.04 / 55.29$

$= 1.32$

Side length for all shapes = 1"

Assembly

Kerfing & Friction Fit

To determine the tolerances I needed, I cut a variety of insert pieces. The input is constant at 0.2", and the outer pieces are changing. I initially tried 0.21" width, and the kerf made the two pieces loose enough for them to never stick together. Afterward, I created a stick of extrusions with a variety of widths, from 0.211" to 0.216". After trial and error, 0.216" was the best fit.

Intrusion: 0.2"
Extrusion: 0.216"

Analysis & Improvements

Analysis

- Designing and prototyping never ends; it's a continual cycle.
 - Sketches allowed me to think every aspect of the project through, from sizing, to connector sizes.
 - Prototypes, especially with a less-structural material, provides valuable insight on manufacturability and challenges the idea at its core of whether or not it is going to work.
- The fabricated components took a lot more trial and error than expected, especially the tolerances.
 - Despite the shapes being symmetrical, the tabs come out different every single time. I didn't know the machines were dependent on which cutter, variability of wood, amount of usage, etc.

Reflection

- I learned the importance of parameters and constraints, and how sketching saves a lot of time in this stage.
- I was heavily debating between having dovetail connectors vs. friction fits until the last minute. However, after creating another cardboard prototype, I realized that unless the pieces were perfectly perpendicular they didn't work, which led me to the friction fit I have now.
- A challenge I ran into was the variability of the cut of the tabs. After the pieces were cut, I noticed that, some of them did not, despite being on the same piece. After realizing that changing the tolerances won't solve the issue, I learned to trust the geometry of the shape, rather than having absolutely perfect connections for every single piece.

Improvements

- I want to find the most ideal overlap for a friction fit. I went to the extent of one hundred thou, but even then, I noticed that some of the parts weren't fitting perfectly.
